

Appointment Capacity Engine

A plain-English guide: what it is, how it works, the tricky cases, and a day-in-the-life example.

1. The problem we are solving

Right now, when you upload a CSV of leads, the system text-messages almost all of them right away. That sounds productive, but here is the catch: you only have a fixed number of agents (say 40), and each agent can handle only so many appointments per day. So if you text 10,000 people, far more of them say "yes, I want an appointment" than your 40 agents can ever meet.

The result:

- Agents get overwhelmed.
- Many interested people cannot get a slot, feel ignored, and you lose them.
- Thousands of good leads get "burned" (used up) for nothing.

In short: you create more demand than you can serve, and the extra leads are wasted.

2. The big idea (think of a restaurant)

Imagine a restaurant with 40 tables. A smart host does NOT let 1,000 people through the door at once. They seat people to fill the tables, keep a short waitlist, and seat more as tables free up. Nobody is turned away for good, no table sits empty, and the kitchen is never buried.

Our engine does the same with leads and appointment slots:

- It counts the "tables" (the appointment slots available today).
- It only "lets in" (texts) enough leads to fill those slots.
- It keeps the rest waiting safely for later.
- It refills any table that opens up.

The system becomes a smart capacity manager instead of a megaphone.

3. How it works, step by step (with a simple example)

Say it is Monday morning and you upload a CSV of 10,000 leads.

- **Step 1 - Count the slots.** The system adds up how many appointment openings all 40 agents have today. Say that is 640 slots.
- **Step 2 - Do the math.** Not everyone you text replies, and not everyone who replies books. From past performance the system knows roughly: about 1 in 5 reply, and about half of those book. So to fill 640 slots it would need a few thousand conversations - but it does NOT send them all at once.
- **Step 3 - Send the first wave.** It picks the BEST leads first (highest score, most likely to buy) and texts a first batch - just enough to get going.
- **Step 4 - Watch and adjust.** As replies and bookings come in, the system watches the calendar fill. Filling slowly? It sends a few more. Filling fast? It sends fewer. This feedback loop speeds up

or slows down on its own.

- **Step 5 - Stop when full.** The moment today's slots are full, the system STOPS texting. The remaining ~9,000 leads are saved, not wasted - ready for tomorrow.

End result: agents fully booked, almost no leads burned.

4. Same-day first

The system always tries to book people for TODAY. Filling today's calendar is the number-one priority. Only if today is completely full does it consider offering tomorrow (see the corner cases).

5. The waitlist (nobody interested is thrown away)

What if someone says "yes" but every slot is already taken? They are NOT discarded. They go on a waitlist with their conversation saved. The moment a slot opens, the waitlisted person is offered it first.

EXAMPLE

All 640 slots are booked by noon. Maria replies "yes" at 12:15, so she joins the waitlist.
At 1:00 PM, someone cancels their 3:00 PM appointment - Maria is instantly offered that 3:00 PM slot.

6. Counting by state (very important)

Agents are licensed by state. A lead in Texas can only meet a Texas-licensed agent. So the engine counts slots and sends leads STATE BY STATE.

EXAMPLE

You have 30 agents licensed in Florida but only 2 in Texas.
The system texts many Florida leads but only a few Texas leads - because Texas can only handle a few appointments.
This avoids getting Texans excited about an appointment no one can actually give them.

7. Fair to agents

The system spreads appointments evenly so no single agent is slammed with 30 calls while others sit idle. Everyone gets a fair share and an equal chance to make sales.

8. A day in the life (the full user flow)

TIMELINE - ONE BUSINESS DAY

9:00 AM - Manager uploads "Monday-leads.csv" (10,000 leads).

9:01 AM - System: "Today's capacity is 640 appointments across 40 agents. Starting with the top leads."

9:00-11:00 AM - Replies arrive. 200 appointments booked. Dashboard shows 31% full.

11:00 AM - Filling a little slowly, so the system sends another small wave of top leads.

1:00 PM - 500 booked. Dashboard: 78% full.

2:00 PM - A few people cancel. Waitlisted leads instantly fill those slots.

3:30 PM - Cutoff time: the system stops sending NEW first texts (so late replies can still get a same-day slot). It keeps booking and refilling.

5:00 PM - 636 of 640 booked = 99% full. About 9,000 leads saved for tomorrow. Wasted leads: near zero.

You did not touch anything after the upload - the engine ran the whole day on its own.

9. Corner cases and how the system handles them

Situation	What the system does
The uploaded list is bigger than capacity	Fills the day, then stops. Extra leads are saved for later, not burned.
The uploaded list is too small to fill the day	Works all of them and alerts you: "Need more leads to fully book today (short by 120)."
A state has no licensed agent	Never texts those leads. Alerts the admin so a license can be added.
Someone replies very late at night	Handled politely, but no new texts go out during quiet hours (legal protection).
Lots of cancellations / no-shows	Freed slots are instantly refilled from the waitlist, then from fresh leads.
People you texted do not reply	The system sends a few more top leads to keep the calendar filling.
CSV uploaded late in the afternoon	Only a partial same-day fill is possible; the dashboard tells you clearly.
Replies come hours later (reply lag)	The system front-loads texts in the morning and stops new texts mid-afternoon, so replies still land while slots exist.
Two people want the same slot	First to confirm gets it; the other is offered the next slot or the waitlist.
Duplicate or opted-out (do-not-contact) leads	Duplicates are merged; do-not-contact people are never texted.
Today is completely full and the waitlist is long	Only then does the system start offering tomorrow's slots - a fallback, not the default.

10. What you see and control

- A live dashboard showing, per state: today's slots, how many are booked, the fill %, how many leads were used, how many were "wasted," and how far you are from full.
- Simple switches you control: turn the engine on or off, set the daily cutoff time, and set what "full" means (for example, 100%).

11. The bottom line

- Agents stay fully booked.
- Same-day appointments stay high.
- Almost no leads are wasted.
- Cancellations are recovered automatically.
- The best leads are used first.
- Outreach speeds up or slows down by itself to match capacity.
- You can drop in a CSV of 10,000 - or 100,000 - leads, and the system calmly uses only what it needs and saves the rest.

It behaves like a smart appointment-filling machine, not a "text everyone and hope" blaster.

12. Coming soon: "Talk to an agent right now"

Today the text invites people to BOOK an appointment for later. The upcoming feature also lets a ready-to-buy person talk to an agent **immediately** - while they are interested - instead of waiting.

How it will work:

- The text adds a line like: "Or reply NOW to talk to an agent right away."
- If the person replies NOW, the system finds an agent who is licensed in their state and free at that moment.
- That agent instantly gets a pop-up notification: "This customer wants a call now - Accept or Decline."
- If the agent accepts, the call connects right away and the person's phone rings.
- If no agent is free, it simply offers to book a normal appointment instead - nobody is left hanging.

EXAMPLE

John gets the text and replies "NOW" at 10:20 AM.

The system sees Agent Sarah is licensed in John's state and is free right now.

Sarah gets a notification, taps Accept, and is connected to John within seconds.

Why it helps: it catches hot customers at the perfect moment, and it keeps agents busy in the gaps between booked appointments - so almost no time is wasted. (This builds on the calling system and will arrive as a later add-on.)

Launchpad / Endeavor - Appointment Capacity Engine - plain-English overview. This describes the planned behavior; nothing in the live system changes until the engine is switched on.
